

# Measure-Preserving Bijective Time Changes of Stationary Gaussian Processes Generates A Subclass of Oscillatory Processes

Stephen Crowley *Email:* [stephencrowley214@gmail.com](mailto:stephencrowley214@gmail.com)

August 1, 2025

## Abstract

This article establishes that Gaussian processes obtained through measure-preserving bijective unitary time transformations of stationary processes constitute a subclass of oscillatory processes in the sense of Priestley[1]. The transformation  $Z(t) = \sqrt{\dot{\theta}(t)}X(\theta(t))$ , where  $X(t)$  is a realization of stationary Gaussian process and  $\theta$  is a strictly increasing  $C^1$  differentiable monotonic function, yields an oscillatory process with evolutionary power spectrum  $dF_t(\omega) = \dot{\theta}(t)d\mu(\omega)$ . An explicit unitary transformation between the input stationary process and the transformed oscillatory process is established, preserving the  $L^2$ -norm and providing a complete spectral characterization.

# 1 Scaling Functions

**Definition 1 (Scaling Functions)** Let  $\mathcal{F}$  denote the set of functions  $\theta : \mathbb{R} \rightarrow \mathbb{R}$  satisfying

1.  $\theta$  is absolutely continuous with

$$\dot{\theta}(t) = \frac{d}{dt}\theta(t) \geq 0 \quad (1)$$

almost everywhere and  $\dot{\theta}(t) = 0$  only on sets of Lebesgue measure zero

2.  $\theta$  is strictly increasing and bijective.

**Remark 1** The conditions in Definition 1 ensure that  $\theta^{-1}$  exists and is absolutely continuous. By the inverse function theorem for absolutely continuous functions,

$$\frac{d}{ds}(\theta^{-1})(s) = \frac{1}{\dot{\theta}(\theta^{-1}(s))} \quad (2)$$

for almost all  $s$  in the range of  $\theta$ . The condition that  $\dot{\theta}(t) = 0$  only on sets of measure zero ensures that  $\frac{1}{\dot{\theta}(\theta^{-1}(s))}$  is well-defined almost everywhere.

# 2 Oscillatory Processes

**Definition 2 (Oscillatory Process)** A complex-valued, second-order process  $\{X(t)\}_{t \in \mathbb{R}}$  is called oscillatory if there exist

1. a family of oscillatory basis functions  $\{\phi_t(\omega)\}_{t \in \mathbb{R}}$  with

$$\phi_t(\omega) = A_t(\omega)e^{i\omega t} \quad (3)$$

and a given gain function

$$A_t(\cdot) \in L^2(\mu) \quad (4)$$

2. and a complex orthogonal random measure  $\Phi(\omega)$  with

$$E|d\Phi(\omega)|^2 = d\mu(\omega) = S(\omega) \quad (5)$$

such that

$$\begin{aligned} Z(t) &= \int_{-\infty}^{\infty} \phi_t(\omega) d\Phi(\omega) \\ &= \int_{-\infty}^{\infty} A_t(\omega)e^{i\omega t} d\Phi(\omega) \end{aligned} \quad (6)$$

All stationary processes are oscillatory with  $A_t(\omega) = 1$

# 3 Stationary Reference Process

Let  $\{X(t)\}_{t \in \mathbb{R}}$  be a stationary Gaussian process with continuous spectral representation

$$X(t) = \int_{-\infty}^{\infty} e^{i\omega t} d\Phi(\omega) \quad (7)$$

where  $\Phi(\omega)$  is an orthogonal-increment process with spectral density

$$E|d\Phi(\omega)|^2 = d\mu(\omega) = S(\omega) = \langle \text{fourier transform of } K_X \rangle \quad (8)$$

and  $\mu$  is a finite measure on  $\mathbb{R}$ .

## 4 Time-Changed Process

### 4.1 Definition and Unitary Operator

**Definition 3 (Unitary Time-Change Operator)** For  $\theta \in \mathcal{F}$ , define the operator  $M_\theta : L^2(\mathbb{R}) \rightarrow L^2(\mathbb{R})$  by

$$(M_\theta f)(t) = \sqrt{\dot{\theta}(t)} f(\theta(t)) \quad (9)$$

**Definition 4 (Unitarily Time-Changed Stationary Process)** For  $\theta \in \mathcal{F}$ , apply the unitary time change operator  $M_\theta$  from Definition 3 to a realization of a stationary process  $X(t)$  from the ensemble  $\{X(t)\}$  to define a realization of the unitarily time-changed process

$$Z(t) = \sqrt{\dot{\theta}(t)} X(\theta(t)) \forall t \in \mathbb{R} \quad (10)$$

**Definition 5 (Inverse Unitary Time-Change Operator)** The inverse operator  $M_\theta^{-1} : L^2(\mathbb{R}) \rightarrow L^2(\mathbb{R})$  corresponding to the unitary time-change operator  $(M_\theta f)(t)$  defined in Equation 9 is given by

$$(M_\theta^{-1} g)(s) = \frac{g(\theta^{-1}(s))}{\sqrt{\dot{\theta}(\theta^{-1}(s))}} \quad (11)$$

**Lemma 1 (Well-Definedness of Inverse Operator)** The operator  $M_\theta^{-1}$  in Definition 5 is well-defined  $\forall \theta \in \mathcal{F}$ .

**Proof** Since  $\dot{\theta}(t) = 0$  only on sets of measure zero by Definition 1, and  $\theta^{-1}$  maps sets of measure zero to sets of measure zero (as it preserves absolute continuity), the denominator  $\sqrt{\dot{\theta}(\theta^{-1}(s))}$  is positive almost everywhere. The expression in equation (11) is therefore well-defined almost everywhere, which is sufficient for defining an element of  $L^2(\mathbb{R})$ .  $\square$

**Theorem 1 (Unitarity of Transformation Operator)** The operator  $M_\theta$  defined in equation (9) is unitary, i.e.,

$$\int_{\mathbb{R}} |(M_\theta f)(t)|^2 dt = \int_{\mathbb{R}} |f(s)|^2 ds \forall f \in L^2(\mathbb{R}) \quad (12)$$

**Proof** Let  $f \in L^2(\mathbb{R})$ . The  $L^2$ -norm of  $M_\theta f$  is computed as follows:

$$\int_{\mathbb{R}} |(M_\theta f)(t)|^2 dt = \int_{\mathbb{R}} \left| \sqrt{\dot{\theta}(t)} f(\theta(t)) \right|^2 dt \quad (13)$$

$$= \int_{\mathbb{R}} \dot{\theta}(t) |f(\theta(t))|^2 dt \quad (14)$$

Apply the change of variables  $s = \theta(t)$ . Since  $\theta$  is absolutely continuous and strictly increasing, its Jacobian is given by

$$ds = \dot{\theta}(t) dt \quad (15)$$

almost everywhere. As  $t$  ranges over  $\mathbb{R}$ ,  $s = \theta(t)$  ranges over  $\mathbb{R}$  due to the bijectivity of  $\theta$ . Therefore:

$$\int_{\mathbb{R}} \dot{\theta}(t) |f(\theta(t))|^2 dt = \int_{\mathbb{R}} |f(s)|^2 ds \quad (16)$$

This establishes equation (12). To complete the proof of unitarity, it remains to show that  $M_{\theta}^{-1}$  is indeed the inverse of  $M_{\theta}$ . For any  $f \in L^2(\mathbb{R})$ :

$$(M_{\theta}^{-1} M_{\theta} f)(s) = (M_{\theta}^{-1}) \left[ \sqrt{\dot{\theta}(\cdot)} f(\theta(\cdot)) \right] (s) \quad (17)$$

$$= \frac{\sqrt{\dot{\theta}(\theta^{-1}(s))} f(\theta(\theta^{-1}(s)))}{\sqrt{\dot{\theta}(\theta^{-1}(s))}} \quad (18)$$

$$= f(s) \quad (19)$$

where the last equality uses  $\theta(\theta^{-1}(s)) = s$ . Similarly, for any  $g \in L^2(\mathbb{R})$ :

$$(M_{\theta} M_{\theta}^{-1} g)(t) = \sqrt{\dot{\theta}(t)} (M_{\theta}^{-1} g)(\theta(t)) \quad (20)$$

$$= \sqrt{\dot{\theta}(t)} \frac{g(\theta^{-1}(\theta(t)))}{\sqrt{\dot{\theta}(\theta^{-1}(\theta(t)))}} \quad (21)$$

$$= \sqrt{\dot{\theta}(t)} \frac{g(t)}{\sqrt{\dot{\theta}(t)}} \quad (22)$$

$$= g(t) \quad (23)$$

Therefore

$$M_{\theta} M_{\theta}^{-1} = M_{\theta}^{-1} M_{\theta} = I \quad (24)$$

proving that  $M_{\theta}$  is unitary.  $\square$

**Corollary 1 (Measure Preservation)** *The transformation  $M_{\theta}$  preserves the  $L^2$ -measure in the sense that for any measurable set  $A \subseteq \mathbb{R}$*

$$\int_A |(M_{\theta} f)(t)|^2 dt = \int_{\theta(A)} |f(s)|^2 ds \quad (25)$$

**Proof** The proof follows the same change of variables argument as in Theorem 1, applied to the characteristic function of the set  $A$ .  $\square$

## 4.2 $L^2$ -Norm Preservation

**Theorem 2 (Measure Preservation)** *The transformation defined in equation (10) preserves the  $L^2$ -norm in the sense that*

$$\int_I \text{var}(Z(t)) dt = \int_{\theta(I)} \text{var}(X(s)) ds \quad (26)$$

for any measurable set  $I \subseteq \mathbb{R}$ .

**Proof** Using the change of variables  $s = \theta(t)$  with  $ds = \dot{\theta}(t) dt$ :

$$\int_I \text{var}(Z(t)) dt = \int_I \text{var} \left( \sqrt{\dot{\theta}(t)} X(\theta(t)) \right) dt \quad (27)$$

$$= \int_I \dot{\theta}(t) \text{var}(X(\theta(t))) dt \quad (28)$$

$$= \int_{\theta(I)} \text{var}(X(s)) ds \quad (29)$$

□

### 4.3 Oscillatory Representation

**Theorem 3 (Oscillatory Form)** *The process  $\{Z(t)\}$  defined in equation (10) is oscillatory with oscillatory functions*

$$\phi_t(\omega) = A_t(\omega) e^{i\omega t} = \sqrt{\dot{\theta}(t)} e^{i\omega\theta(t)} \quad (30)$$

and gain functions

$$A_t(\omega) = \sqrt{\dot{\theta}(t)} e^{i\omega(\theta(t)-t)} \quad (31)$$

**Proof** From the spectral representation (7) of the stationary process  $X(t)$ :

$$Z(t) = \sqrt{\dot{\theta}(t)} X(\theta(t)) \quad (32)$$

$$= \sqrt{\dot{\theta}(t)} \int_{-\infty}^{\infty} e^{i\omega\theta(t)} d\Phi(\omega) \quad (33)$$

$$= \int_{-\infty}^{\infty} \sqrt{\dot{\theta}(t)} e^{i\omega\theta(t)} d\Phi(\omega) \quad (34)$$

$$= \int_{-\infty}^{\infty} \phi_t(\omega) d\Phi(\omega) \quad (35)$$

where

$$\phi_t(\omega) = \sqrt{\dot{\theta}(t)} e^{i\omega\theta(t)} \quad (36)$$

To verify this is an oscillatory representation according to Definition 2, express  $\phi_t(\omega)$  in the form of a function of the time-dependent gain  $A_t(\omega)$  as required

$$\begin{aligned} \phi_t(\omega) &= A_t(\omega) e^{i\omega t} \\ &= \sqrt{\dot{\theta}(t)} e^{i\omega(\theta(t)-t)} e^{i\omega t} \\ &= \sqrt{\dot{\theta}(t)} e^{i\omega(\theta(t)-t+t)} \\ &= \sqrt{\dot{\theta}(t)} e^{i\omega\theta(t)} \end{aligned} \quad (37)$$

where

$$A_t(\omega) = \sqrt{\dot{\theta}(t)} e^{i\omega(\theta(t)-t)} \quad (38)$$

Since  $\dot{\theta}(t) \geq 0$  almost everywhere and  $\dot{\theta}(t) = 0$  only on sets of measure zero, the function  $A_t(\omega)$  is well-defined almost everywhere. Moreover,  $A_t(\cdot) \in L^2(\mu)$  for each  $t$  since:

$$\int_{-\infty}^{\infty} |A_t(\omega)|^2 d\mu(\omega) = \int_{-\infty}^{\infty} \dot{\theta}(t) d\mu(\omega) \quad (39)$$

$$= \dot{\theta}(t) \int_{-\infty}^{\infty} d\mu(\omega) \quad (40)$$

$$= \dot{\theta}(t) \mu(\mathbb{R}) < \infty \quad (41)$$

where the finiteness follows from  $\mu$  being a finite measure and  $\dot{\theta}(t)$  being finite almost everywhere.  $\square$

## 4.4 Envelope and Evolutionary Spectrum

**Corollary 2 (Evolutionary Spectrum)** *The evolutionary power spectrum is*

$$\begin{aligned} dF_t(\omega) &= |A_t(\omega)|^2 d\mu(\omega) \\ &= \dot{\theta}(t) d\mu(\omega) \end{aligned} \quad (42)$$

**Proof** By Definition 2 and the envelope from Equation 4, the evolutionary power spectrum is:

$$dF_t(\omega) = |A_t(\omega)|^2 d\mu(\omega) \quad (43)$$

$$= \left| \sqrt{\dot{\theta}(t)} e^{i\omega(\theta(t)-t)} \right|^2 d\mu(\omega) \quad (44)$$

$$= \dot{\theta}(t) |e^{i\omega(\theta(t)-t)}|^2 d\mu(\omega) \quad (45)$$

$$= \dot{\theta}(t) d\mu(\omega) \quad (46)$$

since

$$|e^{i\alpha}| = 1 \forall \alpha \in \mathbb{R} \quad (47)$$

$\square$

## 5 Operator Conjugation

**Theorem 4 (Operator Conjugation)** *Let  $T_K$  be the integral covariance operator defined by*

$$(T_K f)(t) = \int_{-\infty}^{\infty} K(|t-s|) f(s) ds \quad (48)$$

where  $K(h)$  is the stationary kernel

$$K(h) = \int_{-\infty}^{\infty} S(\lambda) e^{i\lambda h} d\lambda \quad (49)$$

, and let  $T_{K_\theta}$  be the integral covariance operator defined by

$$\begin{aligned} (T_{K_\theta} f)(t) &= \int_{-\infty}^{\infty} K_\theta(s, t) f(s) ds \\ &= \int_{-\infty}^{\infty} K(|\theta(t) - \theta(s)|) \sqrt{\dot{\theta}(t)\dot{\theta}(s)} f(s) ds \end{aligned} \quad (50)$$

for the unitarily time-changed kernel

$$K_\theta(s, t) = K(|\theta(t) - \theta(s)|) \sqrt{\dot{\theta}(t) \dot{\theta}(s)} \quad (51)$$

. Then

$$T_{K_\theta} = M_\theta T_K M_\theta^{-1} \quad (52)$$

**Proof** For any  $g \in L^2(\mathbb{R})$ , compute  $(M_\theta T_K M_\theta^{-1} g)(t)$ :

$$(M_\theta^{-1} g)(s) = \frac{g(\theta^{-1}(s))}{\sqrt{\dot{\theta}(\theta^{-1}(s))}}, \quad (53)$$

$$(T_K M_\theta^{-1} g)(t) = \int_{-\infty}^{\infty} K(|t - s|) \frac{g(\theta^{-1}(s))}{\sqrt{\dot{\theta}(\theta^{-1}(s))}} ds. \quad (54)$$

Apply the change of variables  $u = \theta^{-1}(s)$ , so  $s = \theta(u)$  and  $ds = \dot{\theta}(u) du$ :

$$(T_K M_\theta^{-1} g)(t) = \int_{-\infty}^{\infty} K(|t - \theta(u)|) \frac{g(u)}{\sqrt{\dot{\theta}(u)}} \dot{\theta}(u) du \quad (55)$$

$$= \int_{-\infty}^{\infty} K(|t - \theta(u)|) g(u) \sqrt{\dot{\theta}(u)} du. \quad (56)$$

Now apply  $M_\theta$ :

$$(M_\theta T_K M_\theta^{-1} g)(t) = \sqrt{\dot{\theta}(t)} (T_K M_\theta^{-1} g)(\theta(t)) \quad (57)$$

$$= \sqrt{\dot{\theta}(t)} \int_{-\infty}^{\infty} K(|\theta(t) - \theta(u)|) g(u) \sqrt{\dot{\theta}(u)} du \quad (58)$$

$$= \int_{-\infty}^{\infty} K(|\theta(t) - \theta(u)|) \sqrt{\dot{\theta}(t) \dot{\theta}(u)} g(u) du. \quad (59)$$

Finally, apply the change of variables  $s = u$  (since the integration variable appears as  $u$  in the transformed expression):

$$(M_\theta T_K M_\theta^{-1} g)(t) = \int_{-\infty}^{\infty} K(|\theta(t) - \theta(s)|) \sqrt{\dot{\theta}(t) \dot{\theta}(s)} g(s) ds \quad (60)$$

$$= (T_{K_\theta} g)(t) \quad (61)$$

This establishes the conjugation relation (52).  $\square$

## 6 Expected Zero Count

**Theorem 5 (Expected Zero-Counting Function)** Let  $\theta \in \mathcal{F}$  and let

$$K(\tau) = \text{cov}(X(t), X(t + \tau)) \quad (62)$$

be twice differentiable at  $\tau = 0$ . The expected number of zeros of the process  $Z_t$  in  $[a, b]$  is

$$\mathbb{E}[N_{[a, b]}] = \sqrt{-\ddot{K}(0)} (\theta(b) - \theta(a)) \quad (63)$$

**Proof** The covariance function of the time-changed process is

$$K_\theta(s, t) = \text{cov}(Z_s, Z_t) = \sqrt{\dot{\theta}(s)\dot{\theta}(t)} K(|\theta(t) - \theta(s)|) \quad (64)$$

For the zero-crossing analysis, consider the normalized process. By the Kac-Rice formula:

$$\mathbb{E}[N_{[a,b]}] = \int_a^b \sqrt{-\lim_{s \rightarrow t} \frac{\partial^2}{\partial s \partial t} K_\theta(s, t)} dt \quad (65)$$

Computing the mixed partial derivative:

$$\frac{\partial}{\partial t} K_\theta(s, t) = \frac{1}{2} \frac{\ddot{\theta}(t)}{\sqrt{\dot{\theta}(t)}} \sqrt{\dot{\theta}(s)} K(|\theta(t) - \theta(s)|) \quad (66)$$

$$+ \sqrt{\dot{\theta}(s)\dot{\theta}(t)} \dot{K}(|\theta(t) - \theta(s)|) \text{sgn}(\theta(t) - \theta(s)) \dot{\theta}(t). \quad (67)$$

Taking the limit as  $s \rightarrow t$  and using the fact that  $\dot{K}(0) = 0$  for stationary processes:

$$\lim_{s \rightarrow t} \frac{\partial^2}{\partial s \partial t} K_\theta(s, t) = \dot{\theta}(s)\dot{\theta}(t)\ddot{K}(0) \quad (68)$$

$$= \dot{\theta}(t)^2 \ddot{K}(0) \quad (69)$$

Substituting into the Kac-Rice formula:

$$\mathbb{E}[N_{[a,b]}] = \int_a^b \sqrt{-\dot{\theta}(t)^2 \ddot{K}(0)} dt \quad (70)$$

$$= \sqrt{-\ddot{K}(0)} \int_a^b \dot{\theta}(t) dt \quad (71)$$

$$= \sqrt{-\ddot{K}(0)} (\theta(b) - \theta(a)) \quad (72)$$

Here the second equality uses  $\dot{\theta}(t) \geq 0$  almost everywhere.  $\square$

## 7 Conclusion

This analysis establishes that Gaussian processes generated by measure-preserving bijective time changes of stationary processes form a well-defined subclass of oscillatory processes. The key contributions include:

1. The rigorous construction of the unitary operator  $M_\theta$  and its inverse, with proper treatment of the case where  $\dot{\theta}(t) = 0$  on sets of measure zero.
2. The explicit oscillatory representation with envelope function  $A_t(\omega) = \sqrt{\dot{\theta}(t)} e^{i\omega(\theta(t)-t)}$ .
3. The evolutionary power spectrum formula  $dF_t(\omega) = \dot{\theta}(t) d\mu(\omega)$ .
4. The operator conjugation relationship  $T_{K_\theta} = M_\theta T_K M_\theta^{-1}$ .
5. A closed-form expression for the expected zero count in terms of the range of the time transformation.
