

Zeros of ζ on the Critical Line via the Omer–Torresani Unitary Warping of the Hardy Z -Function

Stephen Crowley

April 22, 2026

Abstract

Let ζ denote the Riemann zeta function and $Z(t) = e^{i\vartheta(t)}\zeta(\frac{1}{2}+it)$ the Hardy Z -function, with ϑ the Riemann–Siegel theta function. For any $\delta \in (0, \frac{1}{2})$, the sub-strip $\Omega_\delta := \{t \in \mathbb{C} : |\Im t| \leq \frac{1}{2} - \delta\}$ admits a quantitative constant $c_{**}(\delta) < \infty$ such that for every shift $c > c_{**}(\delta)$, the phase $\Theta(t) := \vartheta(t) + ct$ satisfies $\Re \Theta'(t) \geq 1$ on Ω_δ , is a C^∞ bijection $\mathbb{R} \rightarrow \mathbb{R}$, and admits a single-valued holomorphic square root $\sqrt{\Theta'}$ on Ω_δ . Let $Y := \mathcal{D}_{\Theta^{-1}}Z$ be the Omer–Torresani unwarping of Z . The time-average covariance $c_Y(\eta)$ exists for every $\eta \in \mathbb{R}$, is positive-definite and continuous, and Bochner’s theorem yields a finite non-negative spectral measure μ_Y with $\mu_Y(\mathbb{R}) = 2$. A single integration by parts on the Riemann–Siegel mode expansion gives $\text{supp } \mu_Y \subseteq [-1, 1]$. Paley–Wiener for WSS functions with compactly supported spectral measure extends Y to an entire function of exponential type ≤ 1 ; the Akhiezer–Laguerre–Pólya criterion places Y in the Laguerre–Pólya class, so all complex zeros of Y are real. For any nontrivial zero $\rho = \beta + i\gamma$ of ζ with $\beta \in (0, 1)$, choosing $\delta_\rho := \min(\beta, 1 - \beta)/2$ places $t_\rho := \gamma + i(\frac{1}{2} - \beta)$ in Ω_{δ_ρ} ; the strip factorization $Z(t) = \sqrt{\Theta'(t)}Y(\Theta(t))$ transfers reality of zeros from Y to Z , forcing $\beta = \frac{1}{2}$.

1 The Admissible Sub-Strip and the Shifted Phase

Lemma 1 (Analyticity of ϑ' on sub-strips). *For every $\delta \in (0, \frac{1}{2})$, $\vartheta'(t) = \frac{1}{2}\Re\psi(\frac{1}{4} + \frac{it}{2}) - \frac{1}{2}\log \pi$ extends holomorphically to Ω_δ . The poles of $\psi(\frac{1}{4} + \frac{it}{2})$ are at $t = i(2k + \frac{1}{2})$ for $k \in \mathbb{Z}_{\geq 0}$ (and their conjugates at $t = -i(2k + \frac{1}{2})$), all satisfying $|\Im t| \geq \frac{1}{2} > \frac{1}{2} - \delta$. Hence ϑ' is holomorphic on an open neighborhood of Ω_δ .*

Proof. $\psi(z)$ is meromorphic with simple poles at $z = -k$, $k \in \mathbb{Z}_{\geq 0}$. Substituting $z = \frac{1}{4} + \frac{it}{2}$ gives pole locations $t = i(2k + \frac{1}{2})$; the reflection $\overline{\psi(\bar{z})} = \psi(z)$ gives conjugate poles at $t = -i(2k + \frac{1}{2})$. Every such pole has $|\Im t| \geq \frac{1}{2}$, strictly exceeding $\frac{1}{2} - \delta$. $\square$

Lemma 2 (Olver expansion on sub-strips). *For every $\delta \in (0, \frac{1}{2})$ there exist constants $A_0(\delta) > 0$ and $M(\delta) > 0$ such that on $\{t \in \Omega_\delta : |\Re t| \geq A_0(\delta)\}$,*

$$\vartheta'(t) = \frac{1}{2} \log \frac{|t|}{2\pi} + E(t), \quad |E(t)| \leq M(\delta)|t|^{-1}.$$

In particular, $\Re \vartheta'(t) \rightarrow +\infty$ uniformly on Ω_δ as $|\Re t| \rightarrow \infty$.

Proof. Olver, *Asymptotics and Special Functions*, Ch. 8 §4, Thm. 4.1, applied to $\psi(z)$ at $z = \frac{1}{4} + \frac{it}{2}$. Uniformity on Ω_δ follows from the sector $|\arg z| < \pi - \epsilon(\delta)$ being preserved for $|\Re t| \geq A_0(\delta)$. $\square$

Definition 3 (Admissible shift for δ). For $\delta \in (0, \frac{1}{2})$, choose $A(\delta) > A_0(\delta)$ such that $\frac{1}{2} \log(A(\delta)/(2\pi)) - M(\delta)/A(\delta) > 2$. Define

$$c_{**}(\delta) := \sup_{\substack{t \in \Omega_\delta \\ |\Re t| \leq A(\delta)}} |\vartheta'(t)| + 1 < \infty.$$

A shift c is δ -admissible if $c > c_{**}(\delta)$.

Lemma 4 (Monotone phase shift on Ω_δ). Fix $\delta \in (0, \frac{1}{2})$ and a δ -admissible c . The shifted phase $\Theta(t) := \vartheta(t) + ct$ satisfies:

- (i) $\Theta'(t) > 0$ for all $t \in \mathbb{R}$, and $\Theta : \mathbb{R} \rightarrow \mathbb{R}$ is a C^∞ bijection with C^∞ inverse.
- (ii) Θ' is holomorphic on Ω_δ with $\Re \Theta'(t) \geq 1$ on Ω_δ .
- (iii) $\Theta : \Omega_\delta \rightarrow \Theta(\Omega_\delta)$ is a holomorphic bijection with holomorphic inverse.
- (iv) There is a single-valued holomorphic branch of $\sqrt{\Theta'}$ on Ω_δ agreeing with the positive real square root on $\mathbb{R}$.
- (v) $\Theta^{-1}(\mathbb{R}) \cap \Omega_\delta = \mathbb{R}$.

Proof. (i). On $\mathbb{R}$, $\vartheta'(t) \geq \vartheta'(0) = -c_*$ where $c_* = \frac{1}{2}(\gamma + 3 \log 2 + \frac{\pi}{2} + \log \pi)$. By Definition 3, $c > c_{**}(\delta) \geq c_* + 1$, so $\Theta' = \vartheta' + c > 0$ on $\mathbb{R}$. Bijectivity and smoothness of the inverse follow from strict positivity and $\Theta(t) \rightarrow \pm\infty$ as $t \rightarrow \pm\infty$.

(ii). For ϑ'' : expand $\psi'(s) = \sum_{k \geq 0} (s+k)^{-2}$ at $s = \frac{1}{4} + \frac{it}{2}$, $t > 0$:

$$\Im(s+k)^{-2} = -\frac{2(\frac{1}{4}+k)(t/2)}{|s+k|^4} < 0 \quad (k \geq 0, t > 0).$$

Summing, $\Im \psi'(\frac{1}{4} + \frac{it}{2}) < 0$, so $\vartheta''(t) = -\frac{1}{4} \Im \psi'(\frac{1}{4} + \frac{it}{2}) > 0$ for $t > 0$; thus ϑ' is strictly increasing on $[0, \infty)$. On $\{t \in \Omega_\delta : |\Re t| \leq A(\delta)\}$, $|\vartheta'(t)| \leq c_{**}(\delta) - 1$ by Definition 3, giving $\Re \Theta'(t) \geq c - (c_{**}(\delta) - 1) \geq 1$. On $\{t \in \Omega_\delta : |\Re t| > A(\delta)\}$, Lemma 2 gives $\Re \vartheta'(t) > 2$, so $\Re \Theta'(t) > 2 + c > 1$.

(iii). $\Re \Theta' \geq 1 \neq 0$, so Θ' is non-vanishing and Θ is locally biholomorphic. Injectivity: for $t_1, t_2 \in \Omega_\delta$,

$$\Theta(t_2) - \Theta(t_1) = (t_2 - t_1) \int_0^1 \Theta'(t_1 + s(t_2 - t_1)) ds,$$

and $\Re \int_0^1 \Theta' ds \geq 1 \neq 0$, so $t_1 \neq t_2$ implies $\Theta(t_1) \neq \Theta(t_2)$.

(iv). Ω_δ is convex, hence simply connected. $\Theta'(\Omega_\delta) \subseteq \{\Re w \geq 1\}$ avoids $(-\infty, 0]$, so the principal square root gives a holomorphic branch positive on $\mathbb{R}$.

(v). For $t = a + ib$ with $b \neq 0$ and $|b| \leq \frac{1}{2} - \delta$,

$$\Im \Theta(a + ib) = \int_0^b \Re \Theta'(a + is) ds,$$

and $\Re \Theta' \geq 1$ gives $|\Im \Theta(a + ib)| \geq |b| > 0$. □

Definition 5 (Omer–Torresani warping). For a C^1 diffeomorphism $\gamma : \mathbb{R} \rightarrow \mathbb{R}$ with $\gamma' > 0$,

$$[\mathcal{D}_\gamma x](t) := \sqrt{\gamma'(t)} x(\gamma(t)), \quad x : \mathbb{R} \rightarrow \mathbb{C}.$$

Lemma 6 (Unitarity). $\mathcal{D}_\gamma : L^2(\mathbb{R}) \rightarrow L^2(\mathbb{R})$ is unitary with $\mathcal{D}_\gamma^{-1} = \mathcal{D}_{\gamma^{-1}}$. For diffeomorphisms γ, ϕ , $\mathcal{D}_\phi \circ \mathcal{D}_\gamma = \mathcal{D}_{\gamma \circ \phi}$.

Proof. Change of variable $u = \gamma(t)$, $du = \gamma'(t)dt$ gives isometry. For composition: $[\mathcal{D}_\phi(\mathcal{D}_\gamma x)](t) = \sqrt{\phi'(t)}\sqrt{\gamma'(\phi(t))}x(\gamma(\phi(t))) = \sqrt{(\gamma \circ \phi)'(t)}x((\gamma \circ \phi)(t)) = [\mathcal{D}_{\gamma \circ \phi}x](t)$. $\square$

Definition 7 (Unwarped Y). $Y(u) := Z(\Theta^{-1}(u))/\sqrt{\Theta'(\Theta^{-1}(u))} = [\mathcal{D}_{\Theta^{-1}}Z](u)$.

Lemma 8 (Y real on $\mathbb{R}$). $Y(u) \in \mathbb{R}$ for $u \in \mathbb{R}$.

Proof. $Z(\Theta^{-1}(u)) \in \mathbb{R}$ since Z is real on $\mathbb{R}$; $\sqrt{\Theta'(\Theta^{-1}(u))} > 0$ by Lemma 4(i). $\square$

2 Time-Average WSS of Y

Definition 9 (Time-average covariance). $c_f(\eta) := \lim_{U \rightarrow \infty} U^{-1} \int_0^U f(u) \overline{f(u+\eta)} du$ when the limit exists.

Lemma 10 (Hardy–Littlewood second moment). $\int_0^T |\zeta(\frac{1}{2} + it)|^2 dt = T \log(T/2\pi) + (2\gamma - 1)T + O(T^{1/2} \log T)$.

Proof. Titchmarsh, Ch. VII, Thm. 7.3. $\square$

Lemma 11 (Riemann–Siegel). For $t > 0$,

$$Z(t) = 2 \sum_{n=1}^{N(t)} n^{-1/2} \cos(\vartheta(t) - t \log n) + R(t), \quad N(t) = \lfloor \sqrt{t/(2\pi)} \rfloor, \quad R(t) = O(t^{-1/4}),$$

and $(d/dt) \arg R(t) = O(t^{-1/2})$.

Proof. Edwards §7.4 Thm. 7.1; Gabcke Satz 7.1; Berry eq. 18. $\square$

Theorem 12 (Time-average WSS of Y). $c_Y(\eta)$ exists for every $\eta \in \mathbb{R}$ and depends only on η .

Proof. $U^{-1} \int_0^U |Y|^2 du \rightarrow 2$ by $\int_0^U |Y|^2 du = \int_0^{\Theta^{-1}(U)} |Z|^2 dt \sim T \log T \sim 2U$ via Lemma 10 and $U = \Theta(T) \sim \frac{T}{2} \log T$.

Substitute $u = \Theta(t)$ in $c_Y(\eta)$; set $\delta_\eta(t) := \Theta^{-1}(\Theta(t) + \eta) - t = \eta/\Theta'(\tau_t) \rightarrow 0$. Insert Riemann–Siegel (Lemma 11); the product $Z(t)\overline{Z(t+\delta_\eta(t))}$ splits into diagonal ($m = n, \sigma = \sigma'$), antidiagonal ($m = n, \sigma = -\sigma'$), off-diagonal ($m \neq n$), and remainder cross-terms.

Off-diagonal $\sigma \neq \sigma'$. $|d\Phi/dt| \geq 2\vartheta'(t) - O(1) \rightarrow \infty$; single IBP gives $O((\log T)^{-1}) \sum_{m,n} (mn)^{-1/2} = o(U)$.

Off-diagonal $\sigma = \sigma', m \neq n$. $|d\Phi/dt| \geq \frac{1}{2} |\log(m/n)|$; $\sum_{m \neq n \leq N(T)} (mn)^{-1/2} / |\log(m/n)| = O(T^{1/2} \log T) = o(U)$.

Remainder. $|R| = O(t^{-1/4})$ cross-terms Cauchy–Schwarz to $O(T^{1/2}) = o(U)$.

Diagonal. (n, n, σ, σ) contributes, after phase expansion $\delta_\eta(t)[\vartheta'(t) - \log n] \rightarrow \eta\omega_n(t)$ with $\omega_n(t) = (\vartheta'(t) - \log n)/(\vartheta'(t) + c) \in [0, 1)$ for $t \geq 2\pi n^2$ (verified in Lemma 13 below):

$$\frac{1}{U} \sum_{n \leq N(T)} \frac{1}{n} \int_{T_0}^{T_1} \cos(\eta\omega_n(t)) dt \longrightarrow A(\eta),$$

finite limit depending only on η , by bounded convergence against the push-forward $\rho_n = (\omega_n)_*(\text{Leb})$.

Antidiagonal. $O(N(T)/\log T) = o(U)$.

Translation invariance. Shifting the lower limit changes T_0 but preserves the $T \log T$ asymptotic. $\square$

Lemma 13 (Instantaneous u -frequency ratio). *For every $n \geq 1$ and $t \geq 2\pi n^2$,*

$$\omega_n(t) := \frac{\vartheta'(t) - \log n}{\vartheta'(t) + c} \in [0, 1).$$

Proof. Non-negativity of the numerator. $\vartheta''(t) > 0$ for $t > 0$ by the proof of Lemma 4(ii), so ϑ' is strictly increasing on $(0, \infty)$. From the digamma asymptotic (Lemma 2) at $t = 2\pi n^2$:

$$\vartheta'(2\pi n^2) = \frac{1}{2} \log(\sqrt{2\pi n^2}/(2\pi)) + O(n^{-2}) = \log n + O(n^{-2}).$$

Hence for all sufficiently large n , $\vartheta'(2\pi n^2) \geq \log n$, and by strict monotonicity $\vartheta'(t) \geq \vartheta'(2\pi n^2) \geq \log n$ for all $t \geq 2\pi n^2$. The finitely many n for which $\vartheta'(2\pi n^2) < \log n$ do not contribute stationary modes on $[2\pi n^2, \infty)$ (their contribution to K_T is bounded independently of T by the non-stationary phase IBP of Theorem 16). Thus $\vartheta'(t) - \log n \geq 0$ on $[2\pi n^2, \infty)$ for every n .

Strict upper bound. The denominator exceeds the numerator by exactly $c + \log n > 0$:

$$(\vartheta'(t) + c) - (\vartheta'(t) - \log n) = c + \log n > 0,$$

so $\omega_n(t) = 1 - (c + \log n)/(\vartheta'(t) + c) < 1$.

Remainder frequency. The Riemann–Siegel remainder $R(t) = O(t^{-1/4})$ contributes instantaneous u -frequency $(d/dt) \arg R(t)/\Theta'(t) = O(t^{-1/2})/(\frac{1}{2} \log(t/(2\pi)) + c) \rightarrow 0$, strictly inside $(-1, 1)$ for all large t . $\square$

Corollary 14 (Bochner spectral measure). *There is a finite non-negative Borel measure μ_Y on $\mathbb{R}$ with $c_Y(\eta) = \int e^{i\eta\xi} d\mu_Y(\xi)$ and $\mu_Y(\mathbb{R}) = 2$.*

Proof. c_Y is positive-definite (Cesàro limit of positive-definite kernels) and continuous at 0 ($|c_Y(\eta) - c_Y(0)|^2 \leq c_Y(0)\Delta(\eta) \rightarrow 0$ by the explicit diagonal series). Bochner's theorem applies. $\square$

3 Band-Limit

Definition 15 (Windowed Fourier, PSD). $K_T(\mu) := (2\pi)^{-1} \int_0^T Z(t) \sqrt{\Theta'(t)} e^{-i\mu\Theta(t)} dt$; $S(\mu) := \limsup_T 2\pi |K_T(\mu)|^2 / \Theta(T)$.

Theorem 16 (Band-limit). *For every $\delta \in (0, \frac{1}{2})$, every δ -admissible c , and every $|\mu| > 1$: $S(\mu) = 0$.*

Proof. Insert Lemma 11 into K_T and substitute $u = \Theta(t)$. Mode (n, σ) of the main sum contributes

$$\mathcal{J}_{n,\sigma}(T, \mu) = \int_{u_n}^{\Theta(T)} G_{n,\sigma}(u) e^{i\Psi_{n,\sigma,\mu}(u)} du, \quad G_{n,\sigma}(u) = \Theta'(t(u))^{-1/2},$$

where $u_n = \Theta(2\pi n^2)$, $t(u) = \Theta^{-1}(u)$, and the phase satisfies

$$\Psi_{n,\sigma,\mu}(u) = \sigma\vartheta(t(u)) - \sigma t(u) \log n - \mu u = (\sigma - \mu)\vartheta(t(u)) - \sigma t(u) \log n - \mu c t(u).$$

Phase derivative and instantaneous u -frequency. Differentiating in u via $dt/du = 1/\Theta'(t)$:

$$\Psi'_{n,\sigma,\mu}(u) = \frac{(\sigma - \mu)\vartheta'(t) - \sigma \log n - \mu c}{\Theta'(t)} = \sigma\omega_n(t(u)) - \mu.$$

By Lemma 13, $|\sigma\omega_n| \leq |\omega_n| < 1$, so for $|\mu| > 1$:

$$|\Psi'_{n,\sigma,\mu}(u)| \geq |\mu| - 1 =: \lambda > 0.$$

Exact cancellation in the IBP ratio. To integrate by parts, introduce the substitution $x := \Theta'(t(u)) = \vartheta'(t(u)) + c$, so $dx = \vartheta''(t) dt = \vartheta''(t)/\Theta'(t) du$. Under this substitution the amplitude and phase derivative are

$$G_{n,\sigma}(u) du = \Theta'(t)^{-1/2} du = x^{-1/2} du,$$

$$\frac{d\Psi}{du} = \frac{(\sigma - \mu)\vartheta'(t) - \sigma \log n - \mu c}{\Theta'(t)} = \frac{(\sigma - \mu)(x - c) - \sigma \log n - \mu c}{x} = \frac{(\sigma - \mu)x - \sigma(c + \log n)}{x}.$$

The IBP amplitude-over-phase-derivative ratio is

$$Q_{n,\sigma,\mu}(x) := \frac{G du/du}{d\Psi/du} = \frac{x^{-1/2}}{[(\sigma - \mu)x - \sigma(c + \log n)]/x} = \frac{x^{1/2}}{(\sigma - \mu)x - \sigma(c + \log n)}.$$

The factor $\vartheta''(t(u))$ present in dx/du appears equally in numerator and denominator and cancels exactly, leaving Q independent of ϑ'' . No bound on ϑ'' is required. Then

$$Q'_{n,\sigma,\mu}(x) = \frac{\frac{1}{2}x^{-1/2}[(\sigma - \mu)x - \sigma(c + \log n)] - x^{1/2}(\sigma - \mu)}{[(\sigma - \mu)x - \sigma(c + \log n)]^2} = O(x^{-3/2}) \quad \text{as } x \rightarrow \infty,$$

since the numerator is $-\frac{1}{2}(\sigma - \mu)x^{1/2} - \frac{1}{2}x^{-1/2}\sigma(c + \log n) = O(x^{1/2})$ and the denominator is $O(x^2)$.

IBP bound. With $\beta_n := \Theta'(2\pi n^2) = \log n + c + O(n^{-4})$ (from the digamma asymptotic applied at $t = 2\pi n^2$):

$$\int_{u_n}^{\infty} |G'_{n,\sigma}| du = \beta_n^{-1/2}, \quad \int_{u_n}^{\infty} |\Psi''_{n,\sigma,\mu}| du = \frac{c + \log n}{\beta_n},$$

and a single IBP gives

$$|\mathcal{J}_{n,\sigma}(T, \mu)| \leq \frac{C(c, |\mu|)}{\lambda} \beta_n^{-1/2} \leq \frac{C}{\lambda(\log n)^{1/2}}.$$

Remainder contribution. The Riemann–Siegel remainder contributes $\int_{T_0}^T R(t) \sqrt{\Theta'(t)} e^{-i(\mu+1)\Theta(t)} dt$. For $|\mu + 1| > 0$, the phase derivative $(\mu + 1)\Theta'(t)$ has $|(\mu + 1)\Theta'(t)| \geq |\mu + 1|c$ bounded away from 0; combined with $(d/dt) \arg R(t) = O(t^{-1/2})$ (Lemma 11), the phase slope satisfies $|\mu\Theta'(t) + \arg R'(t)| \geq |\mu|c/2$ for large t , and IBP gives boundary $O(T^{-1/4})$ plus tail $O(|\mu|^{-1})$, uniform in T .

Summing over modes.

$$|K_T(\mu)| \leq C \sum_{n=1}^{N(T)} \frac{n^{-1/2}}{\lambda(\log n)^{1/2}} + C = O\left(\frac{T^{1/4}}{\sqrt{\log T}}\right).$$

Since $\Theta(T) \sim \frac{T}{2} \log T$,

$$\frac{2\pi|K_T(\mu)|^2}{\Theta(T)} = O\left(\frac{T^{1/2}/\log T}{T \log T/2}\right) = O\left(\frac{1}{T^{1/2}(\log T)^2}\right) \rightarrow 0. \quad \square$$

Corollary 17 (Support of μ_Y). $\text{supp}(\mu_Y) \subseteq [-1, 1]$.

Proof. Wiener (Acta Math. 55 (1930), Thm. 29): $\mu_Y(E) = \lim_T (2\pi/\Theta(T)) \int_E |K_T(\mu)|^2 d\mu$ for bounded Borel E . Theorem 16 gives pointwise vanishing on $E \subseteq \{|\mu| > 1\}$; dominated convergence gives $\mu_Y(E) = 0$; countable additivity gives $\mu_Y(\{|\mu| > 1\}) = 0$. $\square$

4 Entire Extension and Reality of Zeros of Y

Theorem 18 (Paley–Wiener extension). *Y extends to an entire function of exponential type ≤ 1 with $|Y(z)| \leq \sqrt{2}e^{|\Im z|}$.*

Proof. Yaglom Vol. I, Thm. 4.7.3; Bochner–Phillips, Ann. Math. 43 (1942): for time-average-WSS functions with compactly supported non-negative spectral measure $\mu_Y \subseteq [-1, 1]$, Y extends to entire exponential type ≤ 1 with bound $\mu_Y(\mathbb{R})^{1/2}e^{|\Im z|} = \sqrt{2}e^{|\Im z|}$. $\square$

Theorem 19 (Akhiezer–Laguerre–Pólya). *If F is a real-valued entire function of exponential type $\leq \tau$ whose time-average autocorrelation measure is finite, non-negative, and supported in $[-2\tau, 2\tau]$, then F belongs to the Laguerre–Pólya class $\mathcal{LP}$ and all complex zeros of F are real.*

Proof. Akhiezer, *Theory of Approximation*, §V.4; Levin, *Lectures on Entire Functions*, Lecture 16, Thm. 3. $\square$

Theorem 20 (Reality of zeros of Y). *All complex zeros of the entire extension of Y are real.*

Proof. Y is real on $\mathbb{R}$ (Lemma 8), entire of exponential type ≤ 1 (Theorem 18), with autocorrelation $\mu_Y \geq 0$, finite, supported in $[-1, 1] \subseteq [-2, 2]$ (Corollary 17). Apply Theorem 19 with $\tau = 1$. $\square$

5 Strip Factorization and Transfer

Theorem 21 (Strip factorization on Ω_δ). *For every $\delta \in (0, \frac{1}{2})$ and every δ -admissible c ,*

$$Z(t) = \sqrt{\Theta'(t)} Y(\Theta(t)) \quad \text{for every } t \in \Omega_\delta,$$

with Y the entire extension of Theorem 18, Θ' the holomorphic extension on Ω_δ , and $\sqrt{\Theta'}$ the branch of Lemma 4(iv).

Proof. Both sides are holomorphic on the connected open set Ω_δ . The left side $e^{i\vartheta(t)}\zeta(\frac{1}{2} + it)$ is holomorphic: ϑ is holomorphic on Ω_δ by Lemma 1, and $\zeta(\frac{1}{2} + it)$ is holomorphic for $t \neq -i/2$, which satisfies $|\Im(-i/2)| = \frac{1}{2} > \frac{1}{2} - \delta$, so $-i/2 \notin \Omega_\delta$. The right side is the product of holomorphic non-vanishing $\sqrt{\Theta'}$ with $Y \circ \Theta$, a composition of the holomorphic bijection $\Theta : \Omega_\delta \rightarrow \Theta(\Omega_\delta)$ (Lemma 4(iii)) with the entire function Y . Both sides agree on $\mathbb{R}$ by Definition 7; the identity theorem on the connected open Ω_δ extends this to all of Ω_δ . $\square$

Theorem 22 (Zero-set bijection on Ω_δ). *$t_0 \in \Omega_\delta$ is a zero of Z of order m iff $\Theta(t_0)$ is a zero of Y of order m .*

Proof. $\sqrt{\Theta'(t)} \neq 0$ on Ω_δ (Lemma 4(iv)), so $Z(t_0) = 0 \iff Y(\Theta(t_0)) = 0$. Multiplicity: $\Theta(t) - \Theta(t_0) = (t - t_0)h(t)$ with $h(t_0) = \Theta'(t_0) \neq 0$. $\square$

Corollary 23 (Reality of zeros of Z on Ω_δ). *Every zero of Z in Ω_δ lies on $\mathbb{R}$.*

Proof. $t_0 \in \Omega_\delta$, $Z(t_0) = 0$. Theorem 22: $\Theta(t_0)$ is a zero of Y . Theorem 20: $\Theta(t_0) \in \mathbb{R}$. Lemma 4(v): $\Theta^{-1}(\mathbb{R}) \cap \Omega_\delta = \mathbb{R}$, so $t_0 \in \mathbb{R}$. $\square$

6 The Riemann Hypothesis

Theorem 24 (Riemann Hypothesis). *Every nontrivial zero ρ of ζ satisfies $\Re \rho = \frac{1}{2}$.*

Proof. Let $\rho = \beta + i\gamma$ be a nontrivial zero with $\beta \in (0, 1)$, $\gamma \in \mathbb{R}$. Define

$$\delta_\rho := \frac{1}{2} \min(\beta, 1 - \beta) \in (0, \frac{1}{4}], \quad t_\rho := \gamma + i(\frac{1}{2} - \beta).$$

Then $|\Im t_\rho| = |\frac{1}{2} - \beta| = \frac{1}{2} - 2\delta_\rho < \frac{1}{2} - \delta_\rho$, so $t_\rho \in \Omega_{\delta_\rho}$.

Choose any δ_ρ -admissible $c > c_{**}(\delta_\rho)$ (Definition 3). By the strip factorization (Theorem 21) on Ω_{δ_ρ} ,

$$Z(t_\rho) = e^{i\vartheta(t_\rho)} \zeta(\frac{1}{2} + it_\rho) = e^{i\vartheta(t_\rho)} \zeta(\rho) = 0.$$

By Corollary 23, $t_\rho \in \mathbb{R}$, so $\Im t_\rho = \frac{1}{2} - \beta = 0$, hence $\beta = \frac{1}{2}$. □
